In an electric circuit, the electric potential difference between the two terminals of a battery or energy source provides the electric pressure which presses on charge to move them from a location of high pressure (high electric potential) to a location of low pressure (low electric potential). Energy is required to move the fluid uphill.

Electric Circuits Review - Answers #2 - The Physics Classroom

To maintain a charge flow in an electric circuit, at least two requirements must be met: #1: An external energy supply (e.g., battery, wall outlet, generator, etc.) to pump the charge through the internal circuit and establish a potential difference across the circuit.

Electric Circuits and Electric Current - The Physics Classroom

In an electric circuit, the electric potential for a moving charge is gained in the battery and lost in a light bulb (or some resistor found in the external circuit). So the electric potential of a charge is the same for any two points which are not separated by a battery or by a light bulb. (a through d)
